Abstract

This package defines and implements the data type bit set, a vector of bits. The size of the vector may grow dynamically. Individual bits can be manipulated.

1 Documentation

1.1 Introduction

Annotations in the PDF format know entries whose values are integers. This numbers are interpreted as set of flags specifying properties. For example, annotation dictionaries can have a key /F. The bits of its integer value are interpreted the following way:

Bit position	Property name
1	Invisible
2	Hidden
3	Print
4	NoZoom
5	NoRotate
6	NoView
7	ReadOnly
	

Now, let's see how these values are set in package hyperref before it uses this package (before v6.77a):

```
\ifFld@hidden /F 6\else /F 4\fi
```

Where are the other flags? The following example for key /Ff in a widget annotation supports at least three properties:

```
\ifFld@multiline
\ifFld@readonly /Ff 4097\else /Ff 4096\fi
\else
\ifFld@password
\ifFld@readonly /Ff 8193\else /Ff 8192\fi
\else
\ifFld@readonly /Ff 1\fi
\fi
```

But you see the point. It would be a nightmare to continue this way in supporting the missing flag settings. This kind of integers may have up to 32 bits.

Therefore I wanted a data structure for setting and clearing individual bits. Also it should provide an export as decimal number. The snipsets above are executed in expansion contexts without TeX's stomach commands. It would be convenient to have an expandable conversion from the data structure to the integer that gets written to the PDF file.

This package bitset implements such a data structure. The interface is quite close to Java's class BitSet in order not to learn to many interfaces for the same kind of data structure.

1.2 Glossary

Bit set: A bit set is a vector of bits or flags. The vector size is unlimited and grows dynamically. An undefined bit set is treated as bit set where all bits are cleared.

Bit sets are addressed by name. A name should consists of letters or digits. Technically it must survive \csname, see IATEX's environment names for other names with such a constraint. Package babel's shorthands are not supported due to technical reasons. Shorthand support would break expandable operations.

Size: A size of a bit set is the number of bits in use. It's the number of the highest index, incremented by one. Sizes are in the range 0 up to 2147483647, the highest number supported by TeX.

Index: Bit positions in a bit set are addressed by an index number. The bit vector is zero based. The first and least significant bit is addressed by index 0 and the highest possible bit by 2147483646.

Bit: A bit is enoded as 0 for cleared/disabled or 1 for set/enabled.

1.3 Design principles

Name conventions: To avoid conflicts with existing macro names, the operations are prefixed by the package name.

Zero based indexes: The first bit is addressed by zero. (Convention of array indexing in C, Java, ...)

Unlimited size: There is no restriction on the size of a bit set other than usual memory limitations. \bitsetSetDec and \bitsetGetDec transparently switch to package bigintcalc if the numbers get too large for TeX's number limit.

Expandibility: Any operation that does not change the bit set is expandable. And all operations that extract or calculate some result do this in exact two expansion steps. For example, a macro \Macro wants a bit set as decimal number. But the argument must be a plain number without macros. Thus you could prefix \bitsetGetDec with \number. However this won't work for bit sets with 31 or more bits because of T_EX 's number limit of $2^{31} - 1$. then just hit the operator with two \expandafter:

\expandafter\expandafter\expandafter \Macro\bitsetGetDec{foo}

\bitsetGetDec is hit first by the third **\expandafter** and then by the second one.

Format independence: This package is written as LATEX package, but it does not depend on LATEX. It will also work for other formats such as plain TEX.

Independence from T_EX engines: Vanilla T_EX is all you need. Calculations are delegated to packages intcalc and bigintcalc. They don't need any special features, but they will switch to a little more efficient implementation if features such as \numexpr are available.

Numeric arguments: Anything that is accepted by \number. If ε -TeX is detected, also expressions for \numexpr are supported. The only exception so far is the number for \bitsetSetDec. The number might be too large for \number or \numexpr.

Error messages: In expandable contexts, only a limited set of TEX primitive commands work as expected. So called stomach commands behave like \relax and don't get expanded or executed. Unhappily also the error commands belong to this category. The expandable operations will throw an unknown control sequence instead to get TEX's and user's attention. The name of these control sequences starts with \BitSetError: with the type of error after the colon.

1.5 Package loading

The package can be used as normal LATEX package:

\usepackage{bitset}

Also plain T_FX is supported:

\input bitset.sty\relax

1.6 Operators

The following macros work on and with bit sets. A bit set $\langle BitSet \rangle$ is represented by a name. The should consist of letters and digits. Technically it must survive \backslash csname. It is the same constraint that must be satisfied by label or environment names in \LaTeX .

However active characters that are shorthands of package babel are not supported. Support for shorthands works by an assignment. But many operators such

^aMacros are expandable, full expansion by two steps.

^bMacros are expandable.

as \bitsetGetDec must be usable in expandable contexts. There assignments will not be executed in the best case or they will cause errors.

The bits in a bit set are addressed by non-negative integers starting from zero. Thus negative index numbers cause an error message. Because index numbers are TEX numbers. The largest index is 2147483647. But in practice memory limits and patience limits will be very likely reached much before.

1.6.1 Miscellaneous

There isn't a separate operation for bit set creation. For simplicity an undefined bit set is treated as bit set with all bits cleared.

```
\bitsetReset \{\langle BitSet \rangle\}
```

Macro \bitsetReset clears all bits. The result is an empty bit set. It may also be used as replacement for an operation "new", because an undefined bit set is defined afterwards.

```
\bitsetLet \{\langle BitSet \ A \rangle\}\ \{\langle BitSet \ B \rangle\}
```

Macro \bitsetLet performs a simple assignment similar to T_EX 's \let. After the operation $\langle BitSet\ A \rangle$ has the same value as $\langle BitSet\ B \rangle$. If $\langle BitSet\ B \rangle$ is undefined, then $\langle BitSet\ A \rangle$ will be the empty bit set.

Note: If $\langle BitSet A \rangle$ exists, it will be overwritten.

1.6.2 Import

```
\label{eq:linear_state} $$ \begin{array}{l} \text{\color=1.5ex} & (BitSet) & (BinaryNumber) \\ \textbf{\color=1.5ex} & (BitSet) & (OctalNumber) \\ \textbf{\color=1.5ex} & (BitSet) & (HexadecimalNumber) \\ \end{array} $$
```

The numbers are interpreted as bit vectors and the flags in the bit $\langle BitSet \rangle$ set are set accordingly. These numeric arguments are the only arguments where spaces are allowed. Then the numbers are easier to read.

```
\bitsetSetDec \{\langle BitSet \rangle\}\ \{\langle DecimalNumber \rangle\}
```

Macro \bitsetSetDec uses $\langle DecimalNumber \rangle$ to set the bit set $\langle BitSet \rangle$. The numeric argument must expand to a plain number consisting of decimal digits without command tokens or spaces. Internally this argument is expanded only. It cannot be passed to \number or \numexpr, because the number may be too large for them. However \number or \the\numexpr may be used explicitely. This also helps for unexpandable number command tokens or registers (\z@, \@ne, \count@, ...). Also IATeX' \value needs prefixing:

\bitsetSetDec{foo}{\number\value{bar}}

1.6.3 Export

```
\bitsetGetBin \{\langle BitSet \rangle\}\ \{\langle MinSize \rangle\}\ \bitsetGetOct \{\langle BitSet \rangle\}\ \{\langle MinSize \rangle\}\ \bitsetGetHex \{\langle BitSet \rangle\}\ \{\langle MinSize \rangle\}\
```

These macros returns the bit set as binary, octal or hexadecimal number. If the bit size is smaller than $\langle MinSize \rangle$ the gap is filled with leading zeros. Example:

Macro \bitsetGetHex uses the uppercase letters A to F. The catcode of the letters is one of 11 (letter) or 12 (other).

```
\bitsetGetDec \{\langle BitSet \rangle\}
```

Macro \bitsetGetDec returns the bit set $\langle BitSet \rangle$ as decimal number. The returned number can be larger than TeX's number limit of $2^{31}-1$.

1.6.4 Logical operators

\bitsetAnd
$$\{\langle BitSet \ A \rangle\}\ \{\langle BitSet \ B \rangle\}$$

$$A_{\text{new}} := A_{\text{old}} \text{ and } B \qquad (\forall \text{ bits})$$

\bitsetAndNot $\{\langle BitSet A \rangle\}\ \{\langle BitSet B \rangle\}$

$$A_{\text{new}} := A_{\text{old}} \text{ and } (\text{not } B) \qquad (\forall \text{ bits})$$

\bitsetOr $\{\langle BitSet A \rangle\}\ \{\langle BitSet B \rangle\}$

$$A_{\mathrm{new}} := A_{\mathrm{old}} \; \mathrm{or} \; B \qquad (\forall \; \mathrm{bits})$$

\bitsetXor $\{\langle BitSet A \rangle\}\ \{\langle BitSet B \rangle\}$

$$A_{\text{new}} := A_{\text{old}} \text{ xor } B \qquad (\forall \text{ bits})$$

1.6.5 Shifting

```
\bitsetShiftLeft \{\langle BitSet \rangle\} \{\langle ShiftAmount \rangle\}
\bitsetShiftRight \{\langle BitSet \rangle\} \{\langle ShiftAmount \rangle\}
```

A left shift by one is a multiplication by two, thus left shifting moves the flags to higher positions. The new created low positions are filled by zeros.

A right shift is the opposite, dividing by two, movint the bits to lower positions. The number will become smaller, the lowest bits are lost.

If the $\langle ShiftAmount \rangle$ is negative, it reverts the meaning of the shift operation. A left shift becomes a right shift. A $\langle ShiftAmount \rangle$ of zero is ignored.

1.6.6 Bit manipulation

```
\bitsetClear \{\langle BitSet \rangle\} \{\langle Index \rangle\} \bitsetSet \{\langle BitSet \rangle\} \{\langle Index \rangle\} \bitsetFlip \{\langle BitSet \rangle\} \{\langle Index \rangle\}
```

This macros manipulate a single bit in $\langle BitSet \rangle$ addressed by \Index. Macro \bitsetClear disables the bit, \bitsetSet enables it and \bitsetFlip reverts the current setting of the bit.

\bitsetSetValue $\{\langle BitSet \rangle\}\ \{\langle Index \rangle\}\ \{\langle Bit \rangle\}$

Macro \bitsetSetValue puts bit $\langle Bit \rangle$ at position $\langle Index \rangle$ in bit set $\langle BitSet \rangle$. $\langle Bit \rangle$ must be a valid TeX number equals to zero (disabled/cleared) or one (enabled/set).

1.6.7 Bit retrieval

\bitsetGet $\{\langle BitSet \rangle\}\ \{\langle Index \rangle\}$

Macro \bitsetGet extracts the status of the bit at position $\langle Index \rangle$ in bit set $\langle BitSet \rangle$. Digit 1 is returned if the bit is set/enabled. If the bit is cleared/disabled and in cases of an undefined bitset or an index number out of range the return value is 0.

\bitsetNextClearBit $\{\langle BitSet \rangle\}\ \{\langle Index \rangle\}$

Starting at position $\langle Index \rangle$ (inclusive) the bits are inspected. The first position without a set bit is returned. Possible results are decimal numbers: $\langle Index \rangle$, $\langle Index \rangle + 1, ..., (\infty)$

\bitsetNextSetBit $\{\langle BitSet \rangle\}\ \{\langle Index \rangle\}$

Starting at position $\langle Index \rangle$ (inclusive) the bits are inspected and the index position of the first found set bit is returned. If there isn't such a bit, then the result is -1. In summary possible results are decimal numbers: -1, $\langle Index \rangle$, $\langle Index \rangle + 1$, ..., (∞)

\bitsetGetSetBitList $\{\langle BitSet \rangle\}$

Macro \bitsetGetSetBitList is an application for \bitsetNextSetBit. The set bits are iterated and returned as comma separated list of index positions in increasing order. The list is empty in case of an empty bit set.

1.6.8 Bit set properties

\bitsetSize $\{\langle BitSet \rangle\}$

Macro \bitsetSize returns number of bits in use. It is the same as the index number of the highest set/enabled bit incremented by one.

\bitsetCardinality $\{\langle BitSet \rangle\}$

Macro \bitsetCardinality counts the number of set/enabled bits.

1.6.9 Queries

Also the query procedures are expandable. They ask for a piece of information about a bit set and execute code depending on the answer.

\bitsetIsDefined $\{\langle BitSet \rangle\}\ \{\langle Then \rangle\}\ \{\langle Else \rangle\}$

If the bit set with the name $\langle BitSet \rangle$ exists the code given in $\langle Then \rangle$ is executed, otherwise $\langle Else \rangle$ is used.

```
\bitsetIsEmpty \{\langle BitSet \rangle\}\ \{\langle Then \rangle\}\ \{\langle Else \rangle\}
```

If the bit set $\langle BitSet \rangle$ exists and at least one bit is set/enabled, the code in $\langle Then \rangle$ is executed, $\langle Else \rangle$ otherwise.

```
\bitsetEquals \{\langle BitSet\ A\rangle\}\ \{\langle BitSet\ B\rangle\}\ \{\langle Then\rangle\}\ \{\langle Else\rangle\}
```

Both bit sets are equal if and only if either both are undefined or both are defined and represents the same bit values at the same positions. Thus this definition is reflexive, symmetric, and transitive, enough for an equivalent relation.

```
\bitsetIntersects \{\langle BitSet \ A \rangle\}\ \{\langle BitSet \ B \rangle\}\ \{\langle Then \rangle\}\ \{\langle Else \rangle\}
```

If and only if $\langle BitSet A \rangle$ and $\langle BitSet B \rangle$ have at least one bit at the same position that is set, then code part $\langle Then \rangle$ is executed.

```
\bitsetQuery \{\langle BitSet \rangle\}\ \{\langle Index \rangle\}\ \{\langle Then \rangle\}\ \{\langle Else \rangle\}
```

It's just a wrapper for **\bitsetGet**. If the bit at position $\langle Index \rangle$ is enabled, code $\langle Then \rangle$ is called.

2 Implementation

The internal format of a bit set is quite simple, a sequence of digits 0 and 1. The least significant bit is left. A bit set without any flag set is encoded by 0. Also undefined bit sets are treated that way. After the highest bit that is set there are no further zeroes. A regular expression of valid bit sets values:

```
0|[01]*1
1 (*package)
```

4 Installation

4.1 Download

Package. This package is available on CTAN¹:

CTAN:macros/latex/contrib/oberdiek/bitset.dtx The source file.

CTAN:macros/latex/contrib/oberdiek/bitset.pdf Documentation.

Bundle. All the packages of the bundle 'oberdiek' are also available in a TDS compliant ZIP archive. There the packages are already unpacked and the documentation files are generated. The files and directories obey the TDS standard.

CTAN:install/macros/latex/contrib/oberdiek.tds.zip

TDS refers to the standard "A Directory Structure for TEX Files" (CTAN:tds/tds.pdf). Directories with texmf in their name are usually organized this way.

4.2 Bundle installation

Unpacking. Unpack the oberdiek.tds.zip in the TDS tree (also known as texmf tree) of your choice. Example (linux):

unzip oberdiek.tds.zip -d ~/texmf

 $^{^{1} \}verb|http://ctan.org/pkg/bitset|$

Script installation. Check the directory TDS:scripts/oberdiek/ for scripts that need further installation steps. Package attachfile2 comes with the Perl script pdfatfi.pl that should be installed in such a way that it can be called as pdfatfi. Example (linux):

```
chmod +x scripts/oberdiek/pdfatfi.pl
cp scripts/oberdiek/pdfatfi.pl /usr/local/bin/
```

4.3 Package installation

Unpacking. The .dtx file is a self-extracting docstrip archive. The files are extracted by running the .dtx through plain TFX:

```
tex bitset.dtx
```

TDS. Now the different files must be moved into the different directories in your installation TDS tree (also known as texmf tree):

```
bitset.sty \rightarrow tex/generic/oberdiek/bitset.sty
bitset.pdf \rightarrow doc/latex/oberdiek/bitset.pdf
test/bitset-test1.tex \rightarrow doc/latex/oberdiek/test/bitset-test1.tex
test/bitset-test2.tex \rightarrow doc/latex/oberdiek/test/bitset-test3.tex
test/bitset-test3.tex \rightarrow doc/latex/oberdiek/test/bitset-test3.tex
bitset.dtx \rightarrow source/latex/oberdiek/bitset.dtx
```

If you have a docstrip.cfg that configures and enables docstrip's TDS installing feature, then some files can already be in the right place, see the documentation of docstrip.

4.4 Refresh file name databases

If your TEX distribution (teTEX, mikTEX, ...) relies on file name databases, you must refresh these. For example, teTEX users run texhash or mktexlsr.

4.5 Some details for the interested

Unpacking with LATEX. The .dtx chooses its action depending on the format: plain TEX: Run docstrip and extract the files.

LATEX: Generate the documentation.

If you insist on using LATEX for docstrip (really, docstrip does not need LATEX), then inform the autodetect routine about your intention:

```
latex \let\install=y\input{bitset.dtx}
```

Do not forget to quote the argument according to the demands of your shell.

Generating the documentation. You can use both the .dtx or the .drv to generate the documentation. The process can be configured by the configuration file ltxdoc.cfg. For instance, put this line into this file, if you want to have A4 as paper format:

```
\PassOptionsToClass{a4paper}{article}
```

An example follows how to generate the documentation with pdfIATEX:

```
pdflatex bitset.dtx
makeindex -s gind.ist bitset.idx
pdflatex bitset.dtx
makeindex -s gind.ist bitset.idx
pdflatex bitset.dtx
```
